# Lab 06 - Compute TF-IDF and inspect weights

Course: TGS-2026064715 | Maps to: K4; A4

## Goal

Show why common terms receive lower inverse-document weight.

## Data

hotel_reviews.csv contains 120 fictional Singapore hotel and service reviews with dates, channel, rating, sentiment and property. Names and review text are synthetic; no customer records or external credentials are used.

## Steps

1. Open a terminal in this lab folder. Confirm Python 3.10+ with python3 --version.
2. Install the shared requirements from the parent labs/requirements.txt with python3 -m pip install -r ../requirements.txt.
3. Inspect the first rows and column names in hotel_reviews.csv. Check that review_id is unique and sentiment has three classes.
4. Run python3 run.py from this folder. Read the printed output and any files created in output/.
5. Explain how the result supports the lab goal, what a production dataset would add, and one failure or bias risk.

## Acceptance check

The script exits with code 0. Verify that the reported row count is 120. For model labs, inspect the holdout scores rather than training accuracy; for summaries, inspect the exported CSV/PNG.

## Reflection

How would different hotel review wording, label quality, or data leakage change this result?
